## ABSTRACT

Characters differentiating the arthropod trackway *Bifurculapes* from the similar ichnogenera *Lithographus* and *Copeza* include the position, arrangement and orientation of the tracks within the series. Of the five species of *Bifurculapes* originally described, only *Bifurculapes laqueatus* and *Bifurculapes scolopendroideus* are recognized herein; the other three ichnospecies are considered to be nomina dubia or junior subjective synonyms of *Bifurculapes laqueatus*. Two new specimens, recovered from the Early Jurassic East Berlin Formation of the Hartford Basin in Holyoke, Massachusetts, represent only the second unequivocal occurrence of the ichnogenus outside of the Deerfield Basin. *Bifurculapes* is currently known only from the Early Jurassic.

---

## RÉSUMÉ

Les caractéristiques qui différencient la piste d'arthropode *Bifurculapes* des ichnogenres *Lithographus* et *Copeza* similaires sont la position, la disposition et l'orientation des traces à l'intérieur de la série. Parmi les cinq espèces de *Bifurculapes* originalement décrites, seules *Bifurculapes laqueatus* et *Bifurculapes scolopendroideus* sont ici reconnues. Les trois autres ichnoespèces sont considérées comme *nomina dubia* ou comme synonymes subjectifs plus récents de *Bifurculapes laqueatus*. Les deux nouveaux spécimens trouvés dans la formation du Jurassique précoce d'East Berlin dans le bassin de Hartford, à Holyoke, au Massachusetts, représentent seulement la seconde présence sans équivoque de l'ichnogenre à l'extérieur du bassin de Deerfield. À l'heure actuelle, *Bifurculapes* n'est associé qu'au Jurassique précoce.

[Traduit par la rédaction]

## INTRODUCTION

Edward Hitchcock was one of the most important nineteenth century pioneers of ichnology (Häntzschel 1975; Steinbock 1989; Pemberton *et al.* 2007). In a career that spanned nearly three decades, he devoted 11 papers and two books to the trace fossils of the early Mesozoic Hartford and Deerfield basins of Connecticut and Massachusetts (Lull 1953, p. 310). In these works, Hitchcock erected a bewildering array of 94 ichnogenera and 216 ichnospecies for both vertebrate and invertebrate traces (Rainforth 2005), only a few of which are in wide use today. The multitude of names proposed by Hitchcock is part of a larger phenomenon described by Häntzschel (1975, p. W24), who pointed out that the literature includes an excessive number of ichnotaxa, scattered among numerous publications.

The vast size of Hitchcock's ichnotaxonomic list is the result of at least two factors. First, in the absence of standardized nomenclatural rules in the nineteenth century, he discarded at will previously proposed names of some of

his vertebrate ichnotaxa for new, objective synonyms that better fitted his changing view of trace fossil taxonomy (Olsen and Rainforth 2003; Rainforth 2005). Second, as an ichnological pioneer, he lacked standard criteria for establishing ichnotaxa, guidelines for which are only now being established (e.g., Demathieu and Demathieu 2002; Bertling *et al.* 2006; Minter *et al.* 2007). Following the ICZN (Ride *et al.* 1999), Rainforth (2005) addressed the issue of objective synonyms among Hitchcock's ichnotaxa, but the number of remaining taxa — 71 ichnogenera and 185 ichnospecies — is still staggering. Various authors (e.g., Olsen *et al.* 1992; Keighley and Pickerill 1998; Rainforth 2005; Minter and Braddy 2009) have suggested that the number of ichnotaxa could be further reduced by subjective synonymy using modern criteria for evaluating ichnotaxa.

The present study, which constitutes a revision of Hitchcock's ichnogenus *Bifurculapes*, was stimulated by the discovery of two new specimens of this ichnogenus in Holyoke, Massachusetts (Fig. 1). Hitchcock established five ichnospecies within the ichnogenus: *Bifurculapes curvatus* Hitchcock 1865, *Bifurculapes elachistotatus* Hitchcock 1858,

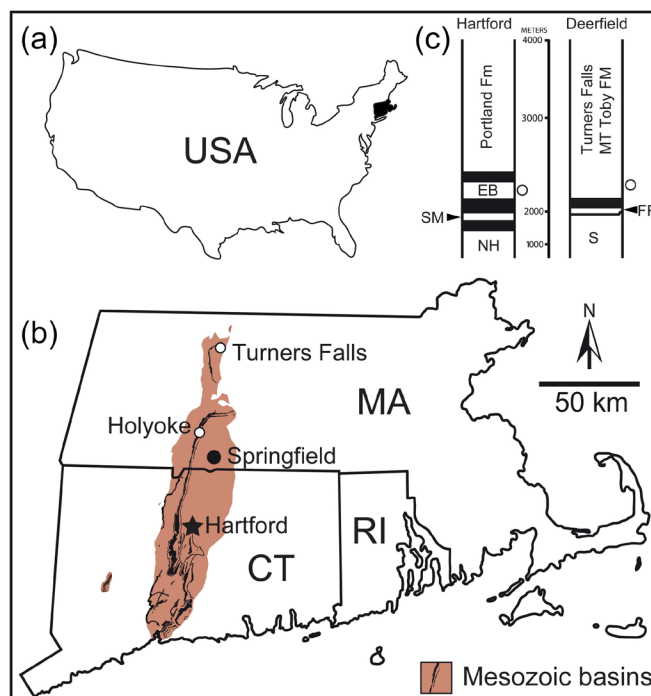

**Figure 1.** One of two newly discovered *Bifurculapes laqueatus* specimens from the Early Jurassic East Berlin Formation of Holyoke, Massachusetts. (a) Overview of the trackway, which is preserved as a natural cast on slab ACM.ICH 300. (b) Photograph and (c) interpretive drawing of the portion of the trackway surrounded by the box in (a). Note the abrupt change in trackway direction. Scale bars are 50 mm in (a) and 10 mm in (b).

*Bifurculapes laqueatus* Hitchcock 1858, *Bifurculapes scolopendroideus* Hitchcock 1858, and *Bifurculapes tuberculatus* Hitchcock 1858. The main focus of this study is to determine whether all of these ichnospecies can be distinguished, or if at least some can be considered subjective synonyms. Additionally, the ichnogenetic diagnosis is revised and tentative criteria for distinguishing *Bifurculapes* from *Lithographus* is provided. More work must be conducted on Hitchcock's other ichnogenera to evaluate further subjective synonymys. Also presented in this paper is a brief discussion of the stratigraphic and geographic distribution of the ichnogenus.

#### GEOLOGICAL AND PALEONTOLOGICAL CONTEXT

The specimens described herein were found in the Hartford and Deerfield basins of southern New England (Fig. 2). These basins are part of the Late Triassic to Early Jurassic Newark Supergroup of eastern North America, which formed as Pangea began to break up; they represent the rifting stage that presaged the opening of the Atlantic Ocean (Olsen 1978, 1997). The rate of crustal extension increased in the Early Jurassic, causing border faults on the eastern margin of the basins to coalesce and form asymmetrical, east-dipping half grabens (Schlische and

**Figure 2.** Geographical and geological context of *Bifurculapes* specimens described herein. (a) Sketch map of the contiguous United States with southern New England shaded black. (b) Map of southern New England states, Connecticut (CT), Massachusetts (MA), and Rhode Island (RI), showing the extent of the early Mesozoic basins and the locations from which *Bifurculapes* has been found. Sedimentary rocks are in light brown; igneous rocks are black. (c) Simplified stratigraphic columns of the Hartford and Deerfield basins showing the approximate positions of the fossil trackways. EB = East Berlin Formation, FR = Fall River beds, NH = New Haven Formation, S = Sugarloaf Formation, SM = Shuttle Meadow Formation.

Olsen 1990). The increased rate of sedimentation caused a change in deposition from fluvial to predominantly lacustrine. The lake deposits exhibit cycles of gray to black shale formed in deep, permanent bodies of water in alternation with red mudstone and sandstone formed in playas. Olsen (1986) attributed the cyclicity to Milankovich cycle-influenced climate changes. Deposition was interrupted during a 600 ka interval by basaltic lava flows (Olsen *et al.* 1996). Models indicate that the paleoclimate was monsoonal (Parrish 1993), with a long dry season (Hubert 1978).

The material that Hitchcock collected came from lacustrine beds of the Early Jurassic Turners Falls Formation in the Deerfield Basin. (Hitchcock 1858, 1865). In particular, the type specimens of *Bifurculapes laqueatus* and *Bifurculapes tuberculatus* were found at Roswell Field's farm, *Bifurculapes curvatus* and *Bifurculapes elachistotatus* were found at the Lily Pond, and *Bifurculapes scolopendroideus*

was found below the cataract in the Connecticut River. As noted by Lull (1953) and Olsen *et al.* (1992), both Field's Farm and the Lily Pond were among the most important of Hitchcock's collecting sites, each yielding large numbers of well-defined vertebrate and invertebrate traces.

The Holyoke, Massachusetts, specimens are from the Hartford Basin and were collected from a privately owned site located at 42°11'51.74"N, 72°38'41.16"W. Nearly two meters of red mudstone and fine-grained sandstone of the Early Jurassic East Berlin Formation are exposed there. Oscillation ripples and mud cracks indicate deposition under playa conditions (Drzewiecki and Zuidema 2007), and sinuous mud cracks on one bed suggest incipient soil formation (Demicco and Gierlowski-Kordesch 1986; Gierlowski-Kordesch and Rust 1994). Vertebrate trace fossils include the theropod tracks *Anchisauripus* sp., *Grallator* sp., and *Eubrontes giganteus*, and the ornithischian track *Anomoepus lactertoideus* (Dalman and Weems 2013; Getty and Fox 2015). Invertebrate tracks, trails and burrows include *Acanthichnus alternans*, *Helminthoidichnites tenuis*, *Planolites* sp., *Skolithos* sp. and *Treptichnus bifurcus* (Getty and Fox 2015, fig. 2; Getty *et al.* 2016). An arthropod resting trace, assigned to the new ichnogenus *Cheliceratichnus*, was possibly made by a sun-spider-like animal (Dalman and Lucas 2015).

## MATERIALS AND METHODS

The 54 trackways examined for this study are housed at the Beneski Museum of Natural History at Amherst College, the Peabody Museum of Natural History at Yale University, and the Science Museum in Springfield, Massachusetts. The abbreviations for these institutions are ACM, YPM and SSM respectively. The acronyms ICH, following ACM, and IP following YPM indicate that the specimens are part of the ichnology collection at the Beneski and the invertebrate paleontology collection at the Peabody. Each specimen was photographed under low-angled light, and measurements were taken from the photographs using the public-domain image-processing and analysis program ImageJ (Rasband 1997–2014). The measurements (Fig. 3) include track length, track width, angle to midline for the track, repeat distance between tracks, inner trackway width, and outer trackway width. Track length is defined herein as a straight line between the anterior and posterior tips of the tracks, whereas width is defined herein as the distance, perpendicular to length, from the line drawn between the tips of the track to the lateralmost point of curvature of the track. Inner and outer trackway widths were recorded from the most medial portion of the tracks in order to avoid spurious values resulting from variations in the angle to the trackway midline. Angles to midline were assigned positive values if the track was oriented posterolaterally and negative values if the track was oriented posteromedially. Morphometric analyses using track length and width were conducted to determine the uniqueness of the various

**Figure 3.** Trackway measurements employed in this study. AtM = angle to midline, IL = inner trackway length, OL = outer trackway length, R = repeat distance (i.e., stride), TL = track length, and TW = track width.

ichnospecies relative to one another.

The systematic ichnology section below is guided by principles for dealing with the taxonomy of arthropod trackways as outlined by Bertling *et al.* (2006) and Minter *et al.* (2007). For example, undertracks and other poorly defined traces are unsuitable to serve as type specimens and are thus considered as *nomen dubium* (Bertling *et al.* 2006, p. 270). Additionally, synonymization is justified for intergrading specimens when the different morphologies represent minor variations within an ethological category, but not when the change in morphology results from changes in behavior that would be considered as different ethological categories (Minter *et al.* 2007, p. 369).

 non 2006 *Bifurculapes*; Santi, p. 205–206, figs. 5 and 6.

TYPE SPECIES: *Bifurculapes laqueatus* Hitchcock 1858, designated by Lull (1953, p. 42).

OTHER SPECIES: *Bifurculapes scolopendroideus* Hitchcock 1858.

EMENDED DIAGNOSIS: A trackway consisting of two rows of elongate, straight or crescentic imprints arranged in series of two, or rarely, three tracks. Within series, the anterior tips of the two larger tracks form a line nearly perpendicular to the trackway midline. Series are arranged in staggered or alternate symmetry. Tracks are of different lengths, with the longest and intermediate length tracks oriented posterolaterally to the trackway axis and often divergent from each other, the smallest track is oriented oblique or perpendicular to the axis. The longest track is almost always on the outside of the trackway, with the middle length track on the inside and the smallest track between the other two.

REMARKS: *Bifurculapes* resembles other ichnogenera erected by Hitchcock, including *Acanthichnus*, *Conopsoides*, *Copeza*, *Grammepus*, *Hamipes*, *Harpagopus*, *Harpepus*, *Lithographus*, *Sagittarius* and *Stratipes* (Minter and Braddy 2009). However, most of these ichnogenera are also in need of revision, which is beyond the scope of this paper; consequently, except for *Lithographus* and *Copeza*, their relationships to *Bifurculapes* will be discussed elsewhere. *Copeza* with *Lithographus* was revised by Minter and Braddy (2009) based on a large number of specimens found in the Permian Robledo Mountains Formation of New Mexico.

*Bifurculapes*, *Lithographus* and *Copeza* can be differentiated from each other by the relative position of the three different tracks within the series and the orientation of the different tracks relative to the trackway midline. In *Bifurculapes*, the outer and inner tracks are nearly parallel to each other and are oblique or parallel to the trackway axis. By contrast, in *Copeza* the outer track is oriented parallel to the trackway midline and the inner track is perpendicular to the trackway midline. In *Lithographus*, the outer track tends to be perpendicular to the trackway midline, whereas the inner or middle track is parallel to the trackway midline (Minter and Braddy 2009; Minter *et al.* 2012).

Further, *Bifurculapes* and *Lithographus* can be differentiated by the relative position and orientation of the different tracks, as defined by their length. In *Lithographus* the longest track is the middle or inner track (Minter and Braddy 2009; Minter *et al.* 2012), whereas in *Bifurculapes* the longest track is on the outside of the trackway. In *Lithographus*, the mid-sized track is oriented perpendicular to the trackway midline, whereas in *Bifurculapes* it is oriented posterolaterally or posteromedially. The smallest track is oriented anterolaterally or parallel to the trackway midline in *Lithographus*, but perpendicular to the trackway axis in *Bifurculapes*. Finally, in *Bifurculapes*, the two longer tracks are located nearly laterally with respect to each other, whereas in *Lithographus* there are distinct anterior, middle, and posterior tracks.

The preservation of medial drags in some specimens, including ACM.ICH 300, indicates that the differences between these two ichnogenera do not result from undertracking (in contrast to the views of Lucas *et al.* 2006 and Minter and Braddy 2009), because these features are the first parts of arthropod trackways lost as a result of undertracking and similar phenomena (e.g., Goldring and Seilacher, 1971; Getty *et al.* 2013).

Hitchcock (1858, 1865) erected five ichnospecies of *Bifurculapes*: *Bifurculapes curvatus*, *Bifurculapes elachistotatus*, *Bifurculapes laqueatus*, *Bifurculapes scolopendroideus* and *Bifurculapes tuberculatus* (Fig. 4). Subsequently, Lull (1953) designated *Bifurculapes laqueatus* as the type species, and thus it has priority in synonymy. Herein, *Bifurculapes curvatus* and *Bifurculapes elachistotatus* are considered to be junior subjective synonyms of *Bifurculapes laqueatus* because their morphologies overlap or intergrade with that of the type ichnospecies. Hitchcock (1865) erected *Bifurculapes curvatus* for specimens in which the tracks were supposedly more curved than in other species. A comparison of *Bifurculapes laqueatus* and *Bifurculapes curvatus* tracks, however, indicates that the difference in track curvature between the two species is negligible (Fig. 5). *Bifurculapes elachistotatus* was differentiated from other species in that its tracks were much shorter and did not touch. Some specimens, however, show that track length varies along the course of individual trackways. For example, both YPM IP 160381 and ACM.ICH 55/62 have sections that would be attributed to *Bifurculapes laqueatus* or *Bifurculapes elachistotatus* if found separately.

In 1865, Hitchcock removed *Bifurculapes tuberculatus* from the ichnogenus, arguing that the specimens on which the species was based were eroded remnants of more complete trackways. The lectotype of *Bifurculapes tuberculatus*, on ACM.ICH 36/19 (Fig. 4i), supports Hitchcock's contention that the ichnospecies is in fact a preservational variant of a more complete trace. The trackway is preserved on two separate laminae; only the distal tips of the tracks are impressed on the overlying lamina, whereas complete tracks are preserved on the underlying lamina. Thus the punctate marks in portions of the lectotype are incomplete overprints. In addition to ACM.ICH 36/19, Hitchcock (1858) listed three other slabs on which *Bifurculapes tuberculatus* was supposedly impressed: ACM.ICH 36/45, 36/46, and 36/47. The species cannot be found, however, on any of these slabs, and Hitchcock (1865) actually identified the trackway on 36/47 as belonging to his new ichnogenus *Pterichnus*. Considering that the lectotype of *Bifurculapes tuberculatus* is a taphonomic variant of a more complete trackway, and that other examples cannot be found on the slabs that represent the type series, this ichnospecies is herein considered to be a *nomen dubium*.

**Figure 4.** Lectotypes of the five ichnospecies of *Bifurculapes* established by Edward Hitchcock, with interpretive line drawings. (a, b) *Bifurculapes laqueatus* on ACM.ICH 36/33. OCCURRENCE: Early Jurassic (Hettangian), Turners Falls Formation of the Deerfield Basin, East Berlin Formation of the Hartford Basin, and Moenave Formation of the Zuni sag.

EMENDED DIAGNOSIS: *Bifurculapes* with two to three tracks per series and a regularly repeating, alternate trackway pattern.

DESCRIPTION: Trackways of this species have external widths from 0.4 to 0.9 cm, and internal widths of 0.1 to 0.5 cm. The tracks are arranged into staggered to alternating series of two to three, and overlap between sets is rare. The position of the third track, where present, is variable, even within a single trackway. It may be positioned anterior or posterior to the other two tracks, or anywhere between; in a lateral direction, this track may occur close to the trackway midline or between the other two. Individual tracks may be straight or curved. Outer track lengths range from 0.5 to 5.4 mm, and inner track lengths are from 0.4 to 4.3 mm. Outer tracks are typically oriented posterolaterally, with angles to midline ranging from 0° to 55°, whereas

**Figure 5.** X-Y scatter plot of track length and width for the ichnospecies *Bifurculapes laqueatus* and *Bifurculapes curvatus*. (a) Measurements for outer tracks. (b) Measurements for inner tracks.

inner tracks are oriented posterolaterally, posteromedially, or parallel to the trackway midline, with angles ranging from  $-37^{\circ}$  to  $32^{\circ}$ . The repeat distance, or stride, ranges from 0.2 to 0.7 cm. Medial drags are rarely present.

REMARKS: As noted previously, the ichnospecies concept for *Bifurculapes laqueatus* is expanded from Hitchcock's (1858) original understanding to include morphologies that he had included in *Bifurculapes curvatus* and *Bifurculapes elachistotatus* because of intergradation among the ichnospecies. *Bifurculapes laqueatus* is retained as the senior synonym because it was designated the type species by Lull (1953).

#### *Bifurculapes scolopendroideus* Hitchcock 1858

(Fig. 4g–h)

- 1858 *Bifurculapes scolopendroideus* E, Hitchcock, p. 153.  
 1865 *Bifurculipes scolopendroideus*; E. Hitchcock, p. 16.  
 1889 *Bifurculipes scolopendroideus*; C.H. Hitchcock, p. 119.  
 1915 *Bifurculapes scolopendroideus*; Lull, p. 58.  
 1953 *Bifurculapes scolopendroideus*; Lull, p. 43.

OCCURRENCE: Early Jurassic (Hettangian), Turners Falls Formation of the Deerfield Basin.

EMENDED DIAGNOSIS: *Bifurculapes* with one to two tracks per series; the inner tracks are only intermittently present. Where present, the inner tracks are oriented either parallel to or inward relative to the trackway midline, and are more irregularly placed than in *Bifurculapes laqueatus* such that the paired series are not always visible.

DESCRIPTION: Trackways assigned to this species have external widths of 1.6 and 2.7 cm, and internal widths of 1.4 and 1.5 cm. Outer track lengths range from 0.6 to 1.3

cm, and inner track lengths from 0.3 to 0.7 cm. The angle to midline for the outer track ranges from  $13$  to  $39^{\circ}$ , that of the inner tracks is  $0$  to  $48^{\circ}$ . The stride of the outer tracks is variable within each trackway, from 0.7 to 2.0 cm in 36/14 and 0.7 to 2.0 cm in 36/41. The short stride length causes overlap, up to 0.3 cm, between some of the tracks in 36/14. Inner tracks are placed medial to, or in line with, the outer tracks relative to the trackway midline, and in some cases are located nearly midway between the outer tracks so that series are not discernable. The close spacing of some of the outer tracks, coupled with the positioning of the inner tracks, sometimes gives the impression of a single, bifurcated trace.

REMARKS: Lull (1953) noted that *Bifurculapes scolopendroideus* exhibits a morphology unlike that of other ichnospecies of *Bifurculapes* in that the inner tracks are not always present, but when they occur they are parallel to the trackway axis. Re-examination of the lectotype confirms Lull's observations: of ten track series on the left side of the trackway that are unequivocally associated with the trace, only two exhibit two tracks. On the right side of the trackway only three, or possibly four, of eleven track series exhibit two tracks. However, the trackway appears to be an undertrack, which might explain the loss of some of the inner tracks. Lull (1953) was skeptical of including *Bifurculapes scolopendroideus* within the ichnogenus but ultimately did not remove it. I share Lull's skepticism but retain its present assignment pending the collection of better specimens.

## DISCUSSION

### Geographic and stratigraphic distribution

Outside of the Hartford and Deerfield basins, tentative occurrences of *Bifurculapes* have been recorded from the Permian of France and Italy (Demathieu *et al.* 1992; Durand 2001; Santi 2006), the Triassic of Argentina (Melchor 2004), the Jurassic of Utah (Lucas *et al.* 2006; Milner *et al.* 2009), and the Cretaceous of Alaska (Fiorillo *et al.* 2009). Many of these trackways, however, are unlike the specimens described by Hitchcock (1858, 1865) and can be assigned to other ichnotaxa, or were not figured. For example, Melchor (2004) and Fiorillo *et al.* (2009) did not figure the specimens that they reported; furthermore, Fiorillo *et al.* were uncertain of the ichnogeneric assignment of the trackways. Additionally, Santi (2006) illustrated trackways that were similar to those reported by Demathieu *et al.* (1992) and Durand (2001). Based on Santi's figure, the trackways appear to have as many as four tracks per series, which would preclude them from inclusion in *Bifurculapes*. As Santi (2006) noted, they might belong to *Secundichnium alternans*, which was erected by Walter (1983). The specimen illustrated by Lucas *et al.* (2006) resembles specimen ACM ICH 55/90 that Hitchcock (1865) attributed to *Bifurculapes curvatus*. Thus, the Utah specimen appears to be the first unequivocal occurrence of

the ichnogenus outside of the Deerfield Basin. Therefore, the specimens from Holyoke, Massachusetts, constitute the second undoubted occurrence of *Bifurculapes* outside of the type region. These three undoubted occurrences of *Bifurculapes* are all of Early Jurassic age.

### Trackmaker

When Hitchcock (1858) first described *Bifurculapes*, he proposed that the likely trackmakers were either arthropods or crustaceans, but he later (1865) considered the fossils to be insect traces. Lull (1915, 1953) concurred with Hitchcock's final assessment and considered insects to be the most likely trackmakers. Most subsequent researchers (e.g., Mayoral 2001) have also suggested that the ichnogenus resulted from insect activity, although Demathieu *et al.* (1992) argued that a triopsid crustacean was a more likely trackmaker for possible specimens from France.

Eiseman and Charney (2010, p. 501) have figured darkling beetle (Coleoptera: Tenebrionidae) trackways that are similar to *Bifurculapes laqueatus* in that the track series sometimes consists of two elongate and posteriorly-oriented tracks, but differ in that the longer track is positioned medially. Overall, however, these modern beetle trackways support the inference that *Bifurculapes laqueatus* was indeed made by an insect. *Bifurculapes scolopendroideus*, on the other hand, is larger and more irregular than *Bifurculapes laqueatus*, and it also occurs in dark grey, lacustrine shale. This latter observation supports the possibility that *Bifurculapes scolopendroideus* may be the trace of a crustacean.

### CONCLUSIONS

The ichnogenus *Bifurculapes*, which represents trackways made by insects, is revised. In addition to the type species, *Bifurculapes laqueatus*, only the ichnospecies *Bifurculapes scolopendroideus* is recognized herein. Three other ichnospecies, *Bifurculapes curvatus*, *Bifurculapes elachistotatus* and *Bifurculapes tuberculatus*, are considered nomina dubia or junior subjective synonyms of *Bifurculapes laqueatus*. Characters differentiating *Bifurculapes* from *Lithographus* and *Copeza* include the position, arrangement, and orientation of the tracks within the series. For example, the outer and inner tracks in *Bifurculapes* are nearly parallel to each other and are oblique or parallel to the trackway midline, whereas in *Lithographus* the inner or middle track is parallel to the midline and the outer track is perpendicular to the midline. In *Copeza*, the inner track is perpendicular to the trackway midline and the outer parallel to the midline. Further, in *Bifurculapes* the largest track is on the outside of the track series, whereas in *Lithographus* it is the middle or inner track. Additionally, in *Bifurculapes* the two larger tracks are lateral to each other, whereas in *Lithographus* the largest track is behind

the middle-sized one. Two new specimens, recovered from the Early Jurassic East Berlin Formation of the Hartford Basin in Holyoke, Massachusetts, represent only the second unequivocal occurrence of the ichnogenus outside of the Deerfield Basin, with the first being from the Jurassic of Utah. Currently, the ichnogenus is known only from the Early Jurassic.

### ACKNOWLEDGMENTS

I thank Sebastian Dalman for bringing the Gary Gaulin Dinosaur Track Site to my attention, and Gary and Laurie Gaulin for granting me permission to study the fossils on their property. I also acknowledge the keen eye of Robert Sproule for finding the *Bifurculapes laqueatus* illustrated in Fig 1. I appreciate the hospitality of Susan Butts, of the Peabody Museum, and Kate Wellspring, formerly of the Beneski Museum of Natural History, during my examination of the specimens in their care. I also thank Richard Sanderson and David Stier of the Springfield Science Museum for accessioning a second *Bifurculapes laqueatus* specimen from Holyoke (SSM 2016/11-4) into their collections. This paper benefited from thorough reviews by Nicholas Minter and Andrew Rindsberg.
