## CHANGE OF PROJECTION BY PROJECTIVE TRANSFORMATION

by Ingénieur hydrographe général de Vanssay de Blavous, Director.

Projective transformation consists in replacing ; in the equations for the coordinates of a projection, $x$ by $\frac{P}{R}$, y by $\frac{Q}{R}$, without changing the axes and putting :-

$$
\begin{aligned}
& P=a x+b y+c ; \\
& Q=d x+e y+f ; \\
& R=m x+n y+p .
\end{aligned}
$$

We will assign Index 1 to the coordinates of the first projection in order to distinguish them from those of the second which shall bear no index. This transformation cannot raise the degree of the curves drawn on the first projection, but the circles will be generally transformed into conics.

The first projection was defined by relations of the form :-

$$
\mathrm{x}_{1}=\varphi(\mathrm{L}, \mathrm{G}), \quad \mathrm{y}_{1}=\psi(\mathrm{L}, \mathrm{G})
$$

in which $L$ represents latitude and $G$ longitude.
The points of the first projection lying on the axis $\mathrm{x}_{1}=0$, will be, in the second, on the straight line $P=0$. Similarly, the points on the axis $y_{1}=0$, will be placed, in the second projection, on the straight line $Q=0$. Lastly, the points that were at infinity in the first projection will be placed on the straight line $R=0$, in the second. This latter property makes it possible to obtain a second projection representing at a convenient distance, an area which was put outside the limits of the chart on the first projection.
I.-Conditions of conformity.

The point $\mathrm{x}, \mathrm{y}$ of the second projection, corresponding to the point $\mathrm{x}_{1}$, $y 1$, of the first will be defined by :

$$
P=R x_{1}, \quad Q=R y 1
$$

Deriving these equations in relation to $L$, we shall have :-

$$
\begin{aligned}
& \mathrm{a} \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}+\mathrm{b} \frac{\delta \mathrm{y}}{\delta \mathrm{~L}}=\left(\mathrm{m} \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}+\mathrm{n} \frac{\delta \mathrm{y}}{\delta \mathrm{~L}}\right) \mathrm{x}_{1}+\mathrm{R} \frac{\delta \mathrm{x}_{1}}{\delta \mathrm{~L}} \\
& \mathrm{~d} \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}+\mathrm{e} \frac{\delta \mathrm{y}}{\delta \mathrm{~L}}=\left(\mathrm{m} \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}+\mathrm{n} \frac{\delta \mathrm{y}}{\delta \mathrm{~L}}\right) \mathrm{y}_{1}+\mathrm{R} \frac{\delta \mathrm{y}_{1}}{\delta \mathrm{~L}} .
\end{aligned}
$$

And similarly, deriving in relation to $G$, and applying the conditions of conformity assumed to be obtained for both projections :-

$$
\mathrm{a} \frac{\delta \mathrm{y}}{\delta \mathrm{~L}}-\mathrm{b} \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}=\left(\mathrm{m} \frac{\delta \mathrm{y}}{\delta \mathrm{~L}}-\mathrm{n} \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}\right) \mathrm{x}_{1}+\mathrm{R} \frac{\delta \mathrm{y}_{1}}{\delta \mathrm{~L}},
$$

$$
\mathrm{d} \frac{\delta \mathrm{y}}{\delta \mathrm{~L}}-\mathrm{e} \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}=\left(\mathrm{m} \frac{\delta \mathrm{y}}{\delta \mathrm{~L}}-\mathrm{n} \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}\right) \mathrm{y}_{1}-\mathrm{R} \frac{\delta \mathrm{x}_{1}}{\delta \mathrm{~L}} .
$$

By eliminating $\frac{\delta \mathrm{x}_{1}}{\delta \mathrm{~L}}$ and $\frac{\delta \mathrm{y}_{1}}{\delta \mathrm{~L}}$ between these four equations, we obtain :-

$$
\begin{aligned}
& \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}\left(\mathrm{mx}_{1}-\mathrm{ny} y_{1}+\mathrm{e}-\mathrm{a}\right)+\frac{\delta \mathrm{y}}{\delta \mathrm{~L}}\left(\mathrm{nx}_{1}+\mathrm{m} y_{1}-\mathrm{b}-\mathrm{d}\right)=\mathrm{o} \\
& \frac{\delta \mathrm{x}}{\delta \mathrm{~L}}\left(\mathrm{nx}_{1}+\mathrm{m} y_{1}-\mathrm{b}-\mathrm{d}\right)-\frac{\delta \mathrm{y}}{\delta \mathrm{~L}}\left(\mathrm{mx}_{1}-\mathrm{ny} y_{1}+\mathrm{e}-\mathrm{a}\right)=\mathrm{o}
\end{aligned}
$$

These two equations can only co-exist if we have :-

$$
\left(m x_{1}-n y_{1}+e-a\right)^{2}+\left(n x_{1}+m y_{1}-b-d\right)^{2}=0
$$

and therefore :-

$$
\begin{aligned}
& m x_{1}-n y_{1}+e-a=0 \\
& n x_{1}+m y_{1}-b-d=0
\end{aligned}
$$

From which we deduce :-
( 1 ) $\mathrm{x}_{1}=\frac{\mathrm{m}(\mathrm{a}-\mathrm{e})+\mathrm{n}(\mathrm{b}+\mathrm{d})}{\mathrm{m}_{2}+\mathrm{n}^{2}}, \quad \mathrm{y}_{1}=\frac{\mathrm{m}(\mathrm{b}+\mathrm{d})-\mathrm{n}(\mathrm{a}-\mathrm{e})}{\mathrm{m}^{2}+\mathrm{n}^{2}}$.
At this point only of the first projection, the second remains conformal if the first were so. This point shall be undeterminated only if $m=n=o$. In this case, we shall indeed see that the second projection remains conformal throughout if the first was so.

## II.-Retaining the circular form.

This retaining of the circular form may be of interest in case a geometric locus, such as a curve of equal azimuth, had a circular form on the first projection.

Let us take a circle on the first projection, whose centre coordinate are : $\alpha_{1}, \beta_{1}$ and radius $r_{1}$. Its equation was therefore :-

$$
\left(x_{1}-\alpha_{1}\right)^{2}+\left(y_{1}-\beta_{1}\right)^{2}=r_{1}^{2} .
$$

It will become by transformation :-
( $\left.\mathrm{I}^{\mathrm{a}}\right) \quad\left(\mathrm{P}-\alpha_{1} \mathrm{R}\right)^{2}+\left(\mathrm{Q}-\beta_{1} \mathrm{R}\right)^{2}=\mathrm{r}_{1}{ }^{2} \mathrm{R}^{2} ;$
whose terms of the second degree are :-
$\left[a x+b y-\alpha_{1}(m x+n y)\right]^{2}+\left[d x+e y-\beta_{1}(m x+n y)\right]^{2}-r_{1}{ }^{2}(m x+n y)^{2}$.
In order that the conic represented by this equation may be a circle, it is necessary that :-

$$
\text { (2) } \begin{aligned}
& \left(a-\alpha_{1} m\right)^{2}+\left(d-\beta_{1} m\right)^{2}-r_{1}^{2} m^{2}=\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}-r_{1}^{2} n^{2}, \\
& \left(a-\alpha_{1} m\right)\left(b-\alpha_{1} n\right)+\left(d-\beta_{1} m\right)\left(e-\beta_{1} n\right)-m n r_{1}^{2}=o,
\end{aligned}
$$

or

$$
\begin{align*}
& \left(\alpha_{1}^{2}+\beta_{1}^{2}-r_{1}^{2}\right)\left(m^{2}-n^{2}\right)-2 \alpha_{1}(a m-b n)-2 \beta_{1}(d m-e n)+a^{2}+d^{2}-b^{2}-e^{2}=0,  \tag{a}\\
& \left(\alpha_{1}^{2}+\beta_{1}{ }^{2}-r_{1}^{2}\right) m n-\alpha_{1}(b m+a n)-\beta_{1}(e m+d n)+a b+d e=0 .
\end{align*}
$$

By eliminating $\alpha_{1}{ }^{2}+\beta_{1}{ }^{2}-r_{1}{ }^{2}$ between these two equations, we obtain the equation (3):-

$$
\begin{equation*}
\alpha_{1}(\mathrm{bm}-\mathrm{an})+\beta_{1}(\mathrm{em}-\mathrm{dn})=\frac{(\mathrm{ab}+\mathrm{ed})\left(\mathrm{m}^{2}-\mathrm{n}^{2}\right)-\left(\mathrm{a}^{2}+\mathrm{d}^{2}-\mathrm{b}^{2}-\mathrm{e}^{2}\right) \mathrm{mn}}{\mathrm{~m}^{2}+\mathrm{n}^{2}} \tag{3}
\end{equation*}
$$

which is the question of the chord common to both circles represented by the equations $2 a$ where $\alpha_{1}$ and $\beta_{1}$ are considered as current coordinates; it no longer contains $r_{1}$. The points $\alpha_{1}, \beta_{1}$, which are concerned, are therefore on the same straight line and at the intersection of this line with one of the circles defined by the equations $2 a$. These points being always real, as we shall show later, there will be for each value of $r_{1}$ two points which may be taken as centres of circles so as to still obtain circles after transformation. There will be nevertheless only one point if the straight line (3) is tangential to the circles ( $2 a$ ).

The square of the radius of the second circle (2a) is equal to :-

$$
\frac{(\mathrm{bm}-\mathrm{an})^{2}+(\mathrm{em}-\mathrm{dn})^{2}}{4 \mathrm{~m}^{2} \mathrm{n}^{2}}+\mathrm{r}_{1}^{2}
$$

On the other hand, the distance from the centre of this circle to the straight line (3) has for its square :-

$$
\left(\frac{m^{2}-n^{2}}{m^{2}+n^{2}}\right)^{2} \frac{(b m-a n)^{2}+(e m-d n)^{2}}{4 m^{2} n^{2}}
$$

a quantity which is obviously less than the preceding one and which will be equal to it only if we have both : $r_{1}=0, \frac{a}{b}=\frac{d}{e}=\frac{m}{n}$.

The two points $\alpha_{1}, \beta_{1}$ are symmetrical on the straight line (3) with respect to the point :-

$$
\mathrm{x}=\frac{\mathrm{am}+\mathrm{bn}}{\mathrm{~m}^{2}+\mathrm{n}^{2}}, \quad \mathrm{y}=\frac{\mathrm{dm}+\mathrm{en}}{\mathrm{~m}^{2}+\mathrm{n}^{2}}
$$

The coordinates will be :-

$$
\alpha_{1}=\frac{m a+n b \pm(m e-n d) \xi}{m^{2}+n^{2}}, \quad \beta_{1}=\frac{m d+n e \mp(m b-n a) \xi}{m^{2}+n^{2}}
$$

(the higher and lower signs are corresponding).
Transferring these values to the second equation (2a), we find :-

$$
\xi^{2}=\mathrm{I}+\frac{\mathrm{r}_{1}^{2}\left(\mathrm{~m}^{2}+\mathrm{n}^{2}\right)}{(\mathrm{mb}-\mathrm{na})^{2}+(\mathrm{me}-\mathrm{nd})^{2}} ;
$$

we shall see later that the negative value must be taken for $\xi$.
The radius of the circle on the second projection will not be null, as a rule, and there will be no conformity of the projection at the point $\alpha_{1}, \beta_{1}$. Instead of determining $\alpha_{1}$ and $\beta_{1}$ their values may be chosen arbitrarily and two of the coefficients of the transformation may be determined by means of the equations ( $2 a$ ). The determination of $m$ and $n$ would generally lead to equations whose resolution might be fairly arduous.

It will be easier to determine $a$ and $d$ or $b$ and $e$. For the first coefficients will be found two values symmetrical with respect to the point :-

$$
\begin{aligned}
& x=m \alpha_{1}+m n r_{1}^{2} \frac{b-\alpha_{1} n}{\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}} \\
& y=m \beta_{1}+m n r_{1}{ }^{2} \frac{e-\beta_{1} n}{\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}}
\end{aligned}
$$

on the straight line :-

$$
x\left(b-\alpha_{1} n\right)+y\left(e-\beta_{1} n\right)=m\left(b \alpha_{1}+e \beta_{1}\right)-m n\left(\alpha_{1}^{2}+\beta_{1}^{2}-r_{1}^{2}\right)
$$

The values of $a$ and $d$ will be -

$$
\begin{aligned}
& a=m \alpha_{1}+m n r_{1}^{2} \frac{b-\alpha_{1} n}{\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}}+\xi\left(e-\beta_{1} n\right), \\
& d=m \beta_{1}+m n r_{1}^{2} \frac{e-\beta_{1} n}{\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}}-\xi\left(b-\alpha_{1} n\right)
\end{aligned}
$$

with

$$
\xi^{2}=1+r_{1}^{2} \frac{m^{2}-n^{2}-\frac{r_{1}^{2} m^{2} n^{2}}{\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}}}{\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}}
$$

For $\xi$ the positive value must be taken.
$b$ and $e$ would be calculated likewise.

$$
\begin{aligned}
& \mathrm{b}=\mathrm{n} \alpha_{1}+\mathrm{mn} \mathrm{r}_{1}^{2} \frac{\mathrm{a}-\mathrm{m} \alpha_{1}}{\left(\mathrm{a}-\mathrm{m} \alpha_{1}\right)^{2}+\left(\mathrm{d}-\mathrm{m} \beta_{1}\right)^{2}}+\zeta\left(\mathrm{d}-\mathrm{m} \beta_{1}\right), \\
& \mathrm{e}=\mathrm{n} \beta_{1}+\mathrm{mn} \mathrm{r}_{\mathrm{l}} \frac{\mathrm{~d}-\mathrm{m} \beta_{1}}{\left(\mathrm{a}-\mathrm{m} \alpha_{1}\right)^{2}+\left(\mathrm{d}-\mathrm{m} \beta_{1}\right)^{2}}-\zeta\left(\mathrm{a}-\mathrm{m} \alpha_{1}\right) .
\end{aligned}
$$

with

$$
\zeta^{2}=1-r_{1}^{2} \frac{m^{2}-n^{2}+\frac{r_{1}^{2} m^{2} n^{2}}{\left(a-m \alpha_{1}\right)^{2}+\left(d-m \beta_{1}\right)^{2}}}{\left(a-m \alpha_{1}\right)^{2}+\left(d-m \beta_{1}\right)^{2}}
$$

For $\zeta$ the negative value must be taken.
In the equations (2a) if the signs of $\alpha_{1}, a$ and $b$, or $\beta_{1}, d$ and $e$, are changed at the same time, the equations do not change.

These equations furnish therefore two values for $\alpha_{1}$, and $\beta_{1}$; which correspond to two values of $a$ and $b$, or $d$ and $e$, which are equal and of opposite signs. If d and e or a and b are given, there will then be only one value to be adopted for $\alpha_{1}$ and $\beta_{1}$.

If, on the contrary, a and b are deduced from the equations (2a) two values will be found for each of these co-efficients, according to whether the positive or negative number will be adopted for $\xi$, from the value of $\xi^{2}$.

Likewise for $b$ and $e$.
Special cases.
I.-If $r_{1}=0, \xi^{3}$ will have the value $\mathrm{I} ; \alpha_{1}$ and $\beta_{1}$ will have the values:-

$$
\alpha_{1}=\frac{\mathrm{ma}+\mathrm{nb} \pm(\mathrm{me}-\mathrm{nd})}{\mathrm{m}^{2}+\mathrm{n}^{2}}, \quad \beta_{1}=\frac{\mathrm{md}+\mathrm{ne} \mp(\mathrm{mb}-\mathrm{na})}{\mathrm{m}^{2}+\mathrm{n}^{2}}
$$

The circle on the second projection will have as equation :-

$$
\mathrm{x}^{2}+\mathrm{y}^{2}-2 \alpha \mathrm{x}-2 \beta \mathrm{y}+\alpha^{3}+\beta^{2}-\rho^{2}=0
$$

with

$$
\begin{aligned}
& \alpha=\frac{\left(\alpha_{1} p-c\right)\left(a-\alpha_{1} m\right)+\left(\beta_{1} p-f\right)\left(d-\beta_{1} m\right)}{\left(a-\alpha_{1} m\right)^{2}+\left(d-\beta_{1} m\right)^{2}} \\
& \beta=\frac{\left(\alpha_{1} p-c\right)\left(b-\alpha_{1} n\right)+\left(\beta_{1} p-f\right)\left(e-\beta_{1} n\right)}{\left(a-\alpha_{1} m\right)^{2}+\left(d-\beta_{1} m_{1}^{2}\right.}
\end{aligned}
$$

$$
\rho^{2}=\frac{\left(\alpha^{2}+\beta^{3}\right)\left[\left(a-\alpha_{1} m\right)^{2}+\left(d-\beta_{1} m\right)^{2}\right]-\left[\left(c-\alpha_{1} p\right)^{2}+\left(f-\beta_{1} p\right)^{2}\right]\left[\left(a-\alpha_{1} m\right)^{2}+\left(d-\beta_{1} m\right)^{2}\right]}{\left[\left(a-\alpha_{1} m\right)^{2}+\left(d-\beta_{1} m\right)^{2}\right]^{2}}
$$

or

$$
\rho^{2}=\frac{\left[\left(\alpha_{1} p-c\right)\left(b-\alpha_{1} n\right)+\left(\beta_{1} p-f\right)\left(e-\beta_{1} n\right)\right]^{2}-\left[\left(\alpha_{1} p-c\right)\left(d-\beta_{1} m\right)-\left(\beta_{1} p-f\right)\left(a-\alpha_{1} m\right)\right]^{2}}{\left[\left(a-\alpha_{1} m\right)^{2}+\left(d-\beta_{1} m\right)^{2}\right]^{2}}
$$

We have also, with the above values of $\alpha_{1}$ and $\beta_{1}$ :-

$$
\begin{aligned}
& b-\alpha_{1} n= \pm\left(d-\beta_{1} m\right) \\
& a-\alpha_{1} m=\mp\left(e-\beta_{1} n\right),
\end{aligned}
$$

Consequently $\rho$ will be null for those values of $\alpha_{1}$ and $\beta_{1}^{-}$, and the second projection will be conformal at this point if the first was so.

With respect to the values of $\alpha_{1}$ and $\beta_{i}^{*}$, the higher and lower signs $\pm$ correspond. We have therefore :-

$$
\alpha_{11}=\frac{\mathrm{m}(\mathrm{a}+\mathrm{e})+\mathrm{n}(\mathrm{~b}-\mathrm{d})}{\mathrm{m}^{2}+\mathrm{n}^{2}}, \quad \beta_{11}=\frac{\mathrm{m}(\mathrm{~d}-\mathrm{b})+\mathrm{n}(\mathrm{a}+\mathrm{e})}{\mathrm{m}^{2}+\mathrm{n}^{2}}
$$

and

$$
\alpha_{12}=\frac{m(a-e)+n(b+d)}{m^{2}+n^{2}}, \quad \beta_{12}=\frac{m(d+b)-n(a-e)}{m^{2}+n^{2}} .
$$

It will be noted that the values of $\alpha_{12}$ and $\beta_{12}$ are identical with those which we indicated for $x$ and $y$ in Chapter I.

If $e$ is changed to - $e$ and $d$ to - $d$, we obtain the value $\alpha_{11}$ and $\beta_{11}$ As, on the other hand, the constant f is not included in these formulae, $\alpha_{11}$ and $\beta_{11}$ will correspond to the transformation :-

$$
\mathrm{x}_{1}=\frac{\mathrm{ax}+\mathrm{by}+\mathrm{c}}{\mathrm{mx}+\mathrm{ny}+\mathrm{p}}, \quad \mathrm{y}_{1}=-\frac{\mathrm{dx}+\mathrm{ey}+\mathrm{f}}{\mathrm{mx}+\mathrm{ny}+\mathrm{p}}
$$

That is to the projection symmetrical to the preceding one about the $\mathrm{x}_{1}$ axis, $\alpha_{12}$ and $\beta_{12}$ being the only values to be adopted.
a and d or b and e might also be calculated for arbitrary values of $a_{1}$ and $\beta_{1}$.

$$
\text { (4) } \begin{aligned}
\mathrm{a} & =\mathrm{m} \alpha_{1}-\beta_{1}+\mathrm{e} \\
\mathrm{~d} & =\mathrm{m} \beta_{1}+\mathrm{n} \alpha_{1}-\mathrm{b}
\end{aligned}
$$

or
(5) $\quad \mathrm{b}=\mathrm{n} \alpha_{1}+\mathrm{m} \beta_{1}-\mathrm{b}$

$$
\mathrm{e}=\mathrm{n} \beta_{1}-\mathrm{m} \dot{\alpha}_{1}+\mathrm{a}
$$

In the first case the transformation will be :-
$\mathrm{x}_{1}=\frac{\left(\mathrm{m} \alpha_{1}-\mathrm{n} \beta_{1}+\mathrm{e}\right) \mathrm{x}+\mathrm{by}+\mathrm{c}}{\mathrm{mx}+\mathrm{ny}+\mathrm{p}}, \quad \mathrm{y}_{1}=\frac{\left(\mathrm{m} \beta_{1}+\mathrm{n} \alpha_{1}-\mathrm{b}\right) \mathrm{x}+\mathrm{ey}+\mathrm{f}}{\mathrm{mx}+\mathrm{ny}+\mathrm{p}}$,
In the second :-
$x_{1}=\frac{\mathrm{ax}+\left(\mathrm{n} \alpha_{1}+\mathrm{m} \beta_{1}-\mathrm{d}\right) \mathrm{y}+\mathrm{c}}{\mathrm{mx}+\mathrm{ny}+\mathrm{p}}, \quad \mathrm{y}_{1}=\frac{\mathrm{dx}+\left(\mathrm{n} \beta_{1}-\mathrm{m} \alpha_{1}+\mathrm{a}\right) \mathrm{y}+\mathrm{f}}{\mathrm{mx}+\mathrm{ny}+\mathrm{p}}$,
We shall thus have, if we determine a and $d:-$

$$
\begin{aligned}
& \mathrm{a}-\alpha_{1} \mathrm{~m}=\mathrm{e}-\mathrm{n} \beta_{\mathrm{t}} \\
& \mathrm{~d}-\beta_{1} \mathrm{~m}=-\left(\mathrm{b}-\mathrm{n} \alpha_{1}\right)
\end{aligned}
$$

and consequently the square of the radius of the circle on the second projection will be :-
$\rho_{2}=\frac{\left[\left(\alpha_{1} p-c\right)\left(b-\alpha_{1} n\right)+\left(\beta_{1} p-f\right)\left(e-\beta_{1} n\right)\right]^{2}-\left[\left(c_{1} p-c\right)\left(b-\alpha_{1} n\right)+\left(\beta_{1} p-f\right)\left(e-\beta_{1} n\right)\right]^{2}}{\left[\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}\right]^{2}}$
We shall again have $p=0$.
It may also be noted that if the values a and $d$ or $b$ and e satisfy these equations, the coordinates $\alpha_{1}$ and $\beta_{1}$ may be chosen arbitrarily and the values which might have been deduced from the equations (I) will be found for a and d or b and e .

Therefore, if the first projection is conformal at the point adopted for $x_{1}, y_{1}$, the second will also be conformal at the point $x, y$, resulting from the transformation, if the equations (I) are verified ; particularly if, $x_{1}$ and $y 1$, being chosen arbitrarily, $a$ and $d$ or $b$ and $e$, or $m$ and $n$ satisfy these equations.

We thus find the values :-

$$
\mathrm{m}=\frac{\alpha_{1}(\mathrm{a}-\mathrm{e})+\beta_{1}(\mathrm{~b}-\mathrm{d})}{\alpha_{1}{ }^{2}+\beta_{1}{ }^{2}}, \quad \mathrm{n}=\frac{\alpha_{1}(\mathrm{~b}+\mathrm{d})-\beta_{1}(\mathrm{a}-\mathrm{e})}{\alpha_{1}{ }^{2}+\beta_{1}{ }^{2}}
$$

which also verify the equations (2a).
We also find for $m$ and $n$ the values $o$, which give finite values for $m$ and $n$ only if :

$$
\mathrm{a}=\mathrm{e} \text { and } \mathrm{b}=-\mathrm{d}
$$

The transformation will then be :-

$$
\mathrm{x}_{1}=\frac{\mathrm{ax}+\mathrm{by}+\mathrm{c}}{\mathrm{p}}, \quad \mathrm{y}_{1}=\frac{-\mathrm{bx}+\mathrm{ay}+\mathrm{f}}{\mathrm{p}}
$$

and we shall have :-

$$
x_{1}+i y_{1}=\frac{(a-b i)(x+i y)+c+f i}{p}
$$

which shows that, in this case, the second projection will be conformal at all the points where the first one was.
II.-If $m=0$, the equations (2) and (3) give :-

$$
\begin{aligned}
& \alpha_{1}=\frac{b}{n}+\frac{d}{n} \sqrt{1+\frac{n^{2} r_{1}^{2}}{a^{2}+\mathrm{d}^{2}}} \\
& \beta_{1}=\frac{e}{n}-\frac{a}{n} \sqrt{I+\frac{n^{2} r_{1}^{2}}{a^{2}+d^{2}}}
\end{aligned}
$$

On the second projection, after transformation, whatever $r_{1}$, may be, these points will be on a straight line parallel to the $y$ axis :-

$$
X=\frac{p(a b+e d)-n(a c+f d)}{n\left(a^{2}+d^{2}\right)}
$$

We may also take $\alpha_{1}$ and $\beta_{1}$ arbitrarily and calculate $a$ and $d$ or $b$ and $e$. We shall have :-

$$
\begin{aligned}
& a=\left(e-\beta_{1} n\right) \xi, \quad \text { with } \xi^{2}=1-\frac{r_{1}^{2} n^{2}}{\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}} \\
& d=\left(b-\alpha_{1} n\right) \xi,
\end{aligned}
$$

by taking the positive value for $\xi$.
It will be necessary that :-

$$
\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2} \geqslant r_{1}^{2} n^{2}
$$

or

$$
\begin{aligned}
& \mathrm{b}=\mathrm{n} \alpha_{1}+\mathrm{d} \zeta, \quad \text { with } \zeta^{2}=\mathrm{I}+\frac{\mathrm{r}_{1}^{2} \mathrm{n}^{2}}{\left(\mathrm{a}-\alpha_{1} \mathrm{~m}\right)^{2}+\left(\mathrm{d}-\beta_{1} \mathrm{~m}\right)^{2}} \\
& \mathrm{e}=\mathrm{n} \beta_{1}-\mathrm{a} \zeta, \quad
\end{aligned}
$$

by taking the negative value for $\zeta$.
III.-If $\mathrm{n}=\mathrm{o}$, we shall have likewise :-

$$
\begin{aligned}
& \alpha_{1}=\frac{a}{m}-\frac{e}{m} \sqrt{1+\frac{m^{2} r_{1}^{2}}{e^{2}+b^{2}}}, \\
& \beta_{1}=\frac{d}{m}+\frac{b}{m} \sqrt{1+\frac{m^{2} r_{1}^{2}}{e^{2}+b^{2}}}
\end{aligned}
$$

and all these points will lie, whatever $r_{1}$ may be, on the second projection, on the parallel to the X axis :-

$$
\mathrm{Y}=\frac{\mathrm{p}(\mathrm{ab}+\mathrm{ed})-\mathrm{m}(\mathrm{bc}+\mathrm{fe})}{\mathrm{m}\left(\mathrm{e}^{2}+\mathrm{b}^{2}\right)}
$$

The equations (2a) become :-

$$
\begin{aligned}
& \left(\alpha_{1}^{2}+\beta_{1}^{2}-r_{1}^{2}\right) m^{2}-2 m\left(a \alpha_{1}+d \beta_{1}\right)+a^{2}+d^{2}-b^{2}-e^{2}=o \\
& \left(\alpha_{1} b+\beta_{1} e\right) m=a b+d e
\end{aligned}
$$

$m$ may be drawn therefrom, if $\alpha_{1}$ and $\beta_{1}$ be considered as known :-

$$
m=\frac{a b+d e}{a_{1} b+\beta_{1} e}
$$

On the other hand, if m is eliminated between the two equations ( $2 a$ ), there comes, after simplification :-

$$
\left(\alpha_{1} \mathrm{~d}-\beta_{1} \mathrm{a}\right)^{2}-\left(\alpha_{1} \mathrm{~b}+\beta_{1} \mathrm{e}\right)^{2}=\mathrm{r}_{2}^{2} \frac{\mathrm{ab}+\mathrm{de}}{\mathrm{e}^{2}+\mathrm{b}^{2}},
$$

which equation shows that, if any value be taken for $m$; the point $\alpha_{1}, \beta_{1}$ must be selected on a hyperbola whose equation is independent of $m$, and at the intersection of this hyperbola with the straight line :-

$$
\alpha_{1} \mathrm{~b}+\beta_{1} \mathrm{e}=\frac{\mathrm{ab}+\mathrm{de}}{\mathrm{~m}}
$$

So, we shall have :-

$$
\begin{aligned}
& m \alpha_{1}=a-e \sqrt{\mathrm{I}+\frac{\mathrm{r}_{1}^{2} \mathrm{~m}^{2}}{\mathrm{e}^{2}+\mathrm{b}^{2}}} \\
& m \beta_{1}=\mathrm{d}+\mathrm{b} \sqrt{\mathrm{I}+\frac{\mathrm{r}_{1}^{2} \mathrm{~m}^{2}}{\mathrm{e}^{2}+\mathrm{b}^{2}}}
\end{aligned}
$$

If $\alpha_{1}$ and $\beta_{1}$, be arbitrarily known, a value of $m$ may be deduced therefrom. If, on the contrary, $m$ be considered as known, $\alpha_{1}$ and $\beta_{1}$, may be deduced therefrom.

We might also calculate $a$ and $d$ and $b$ and $e$ for arbitrary values of $\alpha_{1}$ and $\beta_{1}$ as in the previous case. We shall find :-

$$
\begin{aligned}
& \mathrm{a}=\mathrm{m} \alpha_{1}+\mathrm{e} \sqrt{\mathrm{I}+\frac{\mathrm{r}_{1}^{2} \mathrm{~m}^{2}}{\mathrm{e}^{2}+\mathrm{b}^{2}}} \\
& \mathrm{~d}=\mathrm{m} \beta_{1}-\mathrm{b} \sqrt{\mathrm{I}+\frac{\mathrm{r}_{1}^{2} \mathrm{~m}^{2}}{\mathrm{e}^{2}+\mathrm{b}^{2}}}
\end{aligned}
$$

and likewise for $e$ and $b$.

$$
\begin{aligned}
\text { IV.-If } \mathrm{m}=\mathrm{n}= & \mathrm{o}, \text { the equations (2) will be reduced to :- } \\
& a^{2}+\mathrm{d}^{2}=\mathrm{b}^{2}+\mathrm{e}^{2} \\
& a b+\mathrm{ed}=\mathrm{o}
\end{aligned}
$$

whose solution is :-

$$
\mathrm{d}=-\mathrm{b}, \quad \mathrm{e}=+\mathrm{a}
$$

It may be verified that in this case the transformation will be :-

$$
x_{1}+i y_{1}=\frac{(x+i y)(a-b i)+c+f i}{p}
$$

The second projection remains therefore conformal if the first were so. Only a change of origin, axes and scale, has actually been effected.

$$
\begin{aligned}
& \text { V.-If } \mathrm{a}=\mathrm{d}=\mathrm{o} \text {, the equations }(2 a) \text { and (3) may be written :- } \\
& \qquad \begin{array}{c}
\alpha_{1}^{2}+\beta_{1}^{2}-\mathrm{r}_{1}^{2}=\frac{\mathrm{b}^{2}+\mathrm{e}^{2}}{\mathrm{~m}^{2}+\mathrm{n}^{2}} \\
\\
\\
\alpha_{1} \mathrm{~b}+\beta_{1} \mathrm{e}=\mathrm{n} \frac{\mathrm{~b}^{2}+\mathrm{e}^{2}}{\mathrm{~m}^{2}+\mathrm{n}^{2}}
\end{array}
\end{aligned}
$$

$$
\text { if } \mathrm{m} \text { and } \mathrm{n} \neq \mathrm{o}
$$

from which are deduced :-

$$
\alpha_{1}=\frac{b n}{m^{2}+n^{2}}-\frac{e}{m^{2}+n^{2}} \sqrt{m^{2}+r_{1}^{2} \frac{\left(m^{2}+n^{2}\right)^{2}}{b^{2}+e^{2}}}
$$

$$
\beta_{1}=\frac{e n}{m^{2}+n^{2}}+\frac{b}{m^{2}+n^{2}} \sqrt{m^{2}+r_{1}^{2} \frac{\left(m^{2}+n^{2}\right)^{2}}{b^{2}+e^{2}}}
$$

The circle will then have for equation on the second projection :-
$m^{2}\left(x^{2}+y^{2}\right)\left(b^{2}+e^{2}\right)-2 m x\left[n(b c+e f)-p\left(b^{2}+e^{2}\right)-(e c-b f) \sqrt{m^{2}+r_{1}^{2} \frac{\left(m^{2}+n^{2}\right)^{2}}{b^{2}+e^{2}}}\right]$
$+2 y\left[m^{2}(b c+e f)+n(e c-b f) \sqrt{m^{2}+r_{1}^{2} \frac{\left(m^{2}+n^{2}\right)}{b^{2}+e^{2}}}\right]+\left(m^{2}+n^{2}\right)\left(c^{2}+f^{2}\right)+p^{2}\left(b^{2}+e^{2}\right)$
$-2 \mathrm{p}\left[\mathrm{n}(\mathrm{bc}+\mathrm{ef})-(\mathrm{ec}-\mathrm{bf}) \sqrt{\mathrm{m}^{2}+\mathrm{r}_{1}{ }^{2} \frac{\left(\mathrm{~m}^{2}+\mathrm{n}^{2}\right)^{2}}{\mathrm{~b}^{2}+\mathrm{e}^{2}}}\right]=0$.
It is impossible to have at the same time $\mathrm{a}=\mathrm{d}=\mathrm{b}=\mathrm{e}=\mathrm{o}$, because $\mathrm{x}_{1}, \mathrm{y}_{1}$ ought then to lie on the straight line :

$$
\mathrm{fx}_{1}-\mathrm{ey}_{1}=\mathrm{o}
$$

VI.-If we have besides $\mathrm{n}=\mathrm{o}$; therefore if $\mathrm{a}=\mathrm{d}=\mathrm{n}=\mathrm{o}:-$

$$
\begin{aligned}
& \alpha_{1}=-\frac{e}{m} \sqrt{i+\frac{r_{1}^{2}}{b^{2}+e^{2}}} \\
& \beta_{1}=\frac{b}{m} \sqrt{i+\frac{r_{1}^{2}}{b^{2}+\mathrm{e}^{2}}}
\end{aligned}
$$

The transformation is then :-

$$
\mathrm{x}_{1}=\frac{\mathrm{by}+\mathrm{c}}{\mathrm{mx}+\mathrm{p}}, \quad \mathrm{y}_{1}=\frac{\mathrm{ey}+\mathrm{f}}{\mathrm{mx}+\mathrm{p}}
$$

and the circle equation will be on the second projection :-

$$
\left(x+\frac{p}{m}+\frac{e c-b f}{b^{2}+e^{2}} \sqrt{\left.I+\frac{r_{1}^{2} m^{2}}{b^{2}+e^{2}}\right)^{2}+\left(y+\frac{b c+e f}{b^{2}+e^{2}}\right)^{2}=r_{1}^{2} m^{2} \frac{(e c-b p)^{2}}{\left(b^{2}+e\right)^{2}} . . . . ~}\right.
$$

If $r_{1}=o$, this circle will also have a radius equal to nil; its equation will be:-

$$
\left(x+\frac{p}{m}+\frac{e c-b f}{b^{2}+e^{2}}\right)^{2}+\left(y+\frac{b c+e f}{b^{2}+e^{2}}\right)^{2}=o
$$

and we shall have :-

$$
\alpha_{1}=-\frac{\mathrm{e}}{\mathrm{~m}}, \quad \beta_{1}=\frac{\mathrm{b}}{\mathrm{~m}}
$$

At this point the second projection is still conformal.
It may also be verified that, for this point $\alpha_{1}, \beta_{1}$, we have in this case :-

$$
\left(\alpha_{1}+i \beta_{1}\right)\left[m\left(\alpha_{1}+\beta_{1} i\right)+p\right]=c+i f
$$

VII.-If we have $\frac{m}{n}=\frac{a}{b}=\frac{d}{e}$, without $r_{1}$ being nil, the equations (2a) become :-

$$
\begin{aligned}
& \mathrm{m}^{2}\left(\alpha_{1}^{2}+\beta_{1}^{2}-\mathrm{r}_{1}^{2}\right)+\mathrm{a}^{2}+\mathrm{d}^{2}=0 \\
& \mathrm{~m}^{2}\left(\alpha_{1}^{2}+\beta_{1}^{2}-\mathrm{r}_{1}^{2}\right)-2 \mathrm{~m}\left(\mathrm{a} \alpha_{1}+\mathrm{d} \beta_{1}\right)+\mathrm{a}^{2}+\mathrm{d}^{2}=0
\end{aligned}
$$

which can co-exist only if :-

$$
\mathrm{a} \alpha_{1}+\mathrm{d} \beta_{1}=0
$$

These conditions would require between $\mathrm{x}_{1}$ and $\mathrm{y}_{1}$ the relation－

$$
x_{1}(f n-e p)-y_{1}(c n-b p)=b f+e c
$$

which cannot be contemplated，whether $r_{1}$ be nil or not．
III．－Condions required for a circle to become a straight line．
In order that the conic（ $\mathrm{I} a$ ）may become a straight line through pro－ jective transformation，all the terms of the second degree must have their coefficients equal to nil．We shall therefore have the following equations：－
（6）$\left(a-\alpha_{1} m\right)^{2}+\left(d-\beta_{1} m\right)^{2}=m^{2} r_{1}{ }^{2}$ ，

$$
\left(b-\alpha_{1} n\right)^{2}+\left(e-\beta_{1} n\right)^{2}=n^{2} r_{1}^{2}
$$

$$
\left(a-\alpha_{1} m\right)\left(b-\alpha_{1} n\right)+\left(d-\beta_{1} m\right)\left(e-\beta_{1} n\right)=m n r_{1}^{2}
$$

which may be put in the form ：－

$$
\begin{aligned}
& \text { (6a) } \begin{array}{l}
\alpha_{1}^{2}+\beta_{1}^{2}-\mathrm{r}_{1}^{2}=2 \frac{\mathrm{a} \alpha_{1}+\mathrm{d} \beta_{1}}{m}-\frac{\mathrm{a}^{2}+\mathrm{d}^{2}}{\mathrm{~m}^{2}}=2 \frac{\mathrm{~b} \alpha_{1}+e \beta_{1}}{\mathrm{n}}-\frac{\mathrm{b}^{2}+\mathrm{e}^{2}}{\mathrm{n}^{2}} \\
= \\
=\alpha_{1} \frac{\mathrm{bm}+\mathrm{an}}{\mathrm{mn}}+\beta_{1} \frac{e m+\mathrm{dn}}{m n}-\frac{a b+d e}{m n}
\end{array} .
\end{aligned}
$$

By equating with the last equality half the total of the second and the third，we shall have ：－
（7）$n^{2}\left(a^{2}+d^{2}\right)+m^{2}\left(b^{2}+\mathrm{e}^{2}\right)-2 m n(a b+e d)=0$,
or

$$
(\mathrm{bm}-\mathrm{an})^{2}+(\mathrm{em}-\mathrm{dn})^{2}=0
$$

a relation which can only exist if $m$ and $n$ be different from zero ：－

$$
\frac{\mathrm{a}}{\mathrm{~b}}=\frac{\mathrm{d}}{\mathrm{e}}=\frac{\mathrm{m}}{\mathrm{n}}
$$

The transformation will then be ：－

$$
x_{1}=\frac{a}{m}+\frac{c-a \frac{p}{m}}{m x+n y+p}, \quad y_{1}=\frac{d}{m}+\frac{f-d \frac{p}{m}}{m x+n y+p}
$$

This would require the point $x_{1}, y_{1}$ to lie on an equation straight line ：－

$$
x_{1}\left(f-d \frac{p}{m}\right)-y_{1}\left(c-a \frac{p}{m}\right)+\frac{d c-a f}{m}=o
$$

which cannot be assumed．Consequently，we may see that the conic（ia）will never become a straight line through projective transformation．

If $m$ or $n$ where nil，the transformation would comprise only $y$ or $x$ ， which could not be contemplated．
